LFW

基本思想:将user与item分别表示为一个向量,是UI矩阵分解的方式之一。

用途:

- 计算user的toplike
- 计算item的topsim
- 计算item的topic(对item向量聚类)

建模公式:

$$p^{LFW}(u,i) = p_u^T q_i = \sum\limits_{f=1}^F p_{uf} q_{if}$$

loss function:

$$loss = \sum\limits_{(u,i) \in D} (p(u,i) - p^{LFW}(u,i))^2 + lpha |p_u|^2 + lpha |q_i|^2$$

求偏导:

$$rac{\partial loss}{\partial p_{uf}} = -2(p(u,i)-p^{LFW}(u,i))q_{if} + 2lpha p_{uf}$$

$$rac{\partial loss}{\partial q_{if}} = -2(p(u,i)-p^{LFW}(u,i))p_{uf} + 2lpha q_{if}$$

梯度下降:

$$p_{uf} = p_{uf} - eta rac{\partial loss}{\partial p_{uf}}$$

$$q_{if} = q_{if} - eta rac{\partial loss}{\partial q_{if}}$$

负样本选取规则: 充分展现而用户未点击的样本。
